Healthy People 2030 defines health disparities as “a particular type of health difference that is closely linked with social, economic, and/or environmental disadvantage.” Bladder cancer is the sixth most common cancer in the United States and is primarily a disease of White males 55 years and older. However, disparities in evaluation, management, and mortality persist in patient populations where bladder cancer is less common. It is critical for multidisciplinary care teams to be aware of these disparities in order to effectively reach underserved patient populations.

This article explores disparities in bladder cancer, including data collected through a 2021 Bladder Cancer Economic Study by the Association of Community Cancer Centers (ACCC). It offers practical and operational tips for oncology care team members to manage underserved patients with bladder cancer.

**Delays in Diagnosis**
Blood in the urine, or hematuria, is often the first sign of bladder cancer, and timely referral for urologic evaluation is considered a quality benchmark in bladder cancer management. Compared with males and White patients, females and Black patients are less likely to receive timely diagnostic evaluation of hematuria (Figure 1, page 3).

ACCC recently analyzed Medicare claims data between 2016 and 2019 for patients diagnosed with bladder cancer in 2018 (n=4,356). Results of the analysis show Black, Asian, Hispanic, and North American Native patients are diagnosed later when compared to White patients (Figure 2, page 3).

Stage at diagnosis is a critical determinant of outcomes in bladder cancer and an important measure of outcome disparities. Being female, Black, Hispanic, of low socio-economic status, or lower education level (e.g., high school diploma) are associated with an increased risk of being diagnosed with advanced disease at presentation.

Black patients have up to 10 percent worse disease-specific survival than White patients and are more likely than White patients to die from bladder cancer within three years of diagnosis. Compared with men, women have a greater risk of recurrence and worse overall survival.

The COVID-19 pandemic reduced the number of patients presenting for symptoms suspicious for bladder cancer (e.g., hematuria), and for routine care. At the same time, clinicians are seeing patients from a wider geographic area, especially in relation to complications. These trends are likely to further exacerbate disparities in bladder cancer.

**Treatment and Outcome Disparities**
Medicare claims data research showed a longer time to initial treatment for Asian, Hispanic, North American Native, and Black patients versus White patients in both early- and late-stage bladder cancer (Figure 3, page 4).

Disparities also exist during treatment. Analysis of treatment patterns reveals:

- Women receive fewer cystoscopies than men in many parts of the United States, and are likely to undergo definitive curative radical cystectomy than men.
Black patients have 21 percent lower odds of receiving guideline-based treatment compared to White or Hispanic patients.10
Women, Black patients, those in lower socio-economic regions or with less education are less likely than White patients to receive any treatment or receive treatment within 12 weeks of diagnosis.9
Patients living in rural areas and of lower socio-economic status are less likely to receive neoadjuvant chemotherapy and more likely to experience delays in surgery.11

Most deaths from bladder cancer occur within the first two to four years from diagnosis, making this a critical window for treatment.3 The 5-year relative survival rate for bladder cancer is 77 percent overall, compared to 64 percent for Black patients.12 Women have a lower survival rate than men after radical cystectomy.13

The Financial Toll of Disparities on Patients
There are substantial all-cause healthcare and out-of-pocket costs involved in delaying diagnosis and treatment of bladder cancer. The later the diagnosis, the higher the cost to patients in terms of both financial toxicity and distress. Heather Honoré Goltz, PhD, LCSW, MEd, an oncology social worker, researcher, and health education specialist at the University of Houston-Downtown, emphasizes that patients with bladder cancer without insurance are especially likely to be distressed and anxious about practical concerns, such as the cost of treatment, transportation issues, time off from work, and an available support system for advanced treatment. She observes that when clinicians are mapping patient concerns:

> Oftentimes it’s not the symptomology that is the most disturbing thing to them. It really is, “Am I going to bankrupt my family? Am I going to be able to live and pay my bills? Am I going to be able to keep a roof over my head?”

Heather Honoré Goltz, PhD, LCSW, MEd

Factors Contributing to Disparities in Bladder Cancer
A cluster of factors contribute to disparities in diagnosis, treatment, and outcomes for underserved populations (Figure 2). According to studies in bladder and other types of cancer, type of insurance, the type of hospital providing care, provider density, and travel burden to a center of excellence or academic center are associated with a decreased likelihood of receiving critical treatment,14 regardless of insurance status. Access to care is a key factor in racial disparities in bladder cancer (Figure 4, page 5).

10 Tips to Mitigate Disparities in Bladder Cancer
Multidisciplinary and shared care management of patients with bladder cancer has emerged as a care model associated with quality improvement in oncology care.15 This involves care coordination between oncology and urology practices to support timely referral, specialist evaluation, and survivorship care planning.

The following strategies can help improve outcomes for underserved patient populations and elevate equity in cancer care delivery:

1. Consider bladder cancer as a potential diagnosis in Black and female patients with hematuria who are referred to oncology via primary care, OB/GYN, and emergency rooms.
2. Promptly refer patients with hematuria to urology for timely full urologic evaluation.
3. Screen patients for financial distress at diagnosis. Refer to the ACCC Financial Advocacy Playbook for guidance.16
4. Refer patients to financial advocates or navigators before treatment initiation and at treatment milestones to identify appropriate financial navigation interventions. The ACCC Patient Assistance & Reimbursement Guide can streamline this process.17
5. Practice culturally competent/health literacy communication and shared decision-making to keep patients engaged in their care. Ask Me 3® is a great place to start.18
6. Consider exploring disparities in bladder cancer in your organization via a National Cancer Institute (NCI) Community Oncology Research Program, community-based participatory research study via the NCI Center to Reduce Cancer Health Disparities, or quality improvement project.
7. Build relationships that support access to care and reduce delays in referral through community outreach with primary care, obstetrics/gynecology, and urology providers.
8. Consider concurrent consultation with urology and medical and radiation oncology, as well as shared decision-making between patients and other members of the care team, including oncology nurses, wound ostomy and continence nurses, and oncology social workers.30
9. Provide information and education to patients with cancer at the time of diagnosis about the different treatment types for type and stage of bladder cancer, options for clinical trial participation, and the roles and responsibilities of providers at different points in treatment.
10. Guide patients toward advocacy organizations, such as the Bladder Cancer Advocacy Network, and resources on bladder cancer.
FIGURE 1. Disparities in Time to Diagnosis

- Women may wait two to four weeks longer than men to receive a complete hematuria evaluation.20
- Women are less likely to be referred to a urologist or receive complete evaluation for hematuria.21
- Black patients are less likely to receive timely diagnostic evaluation of hematuria.22
- Black women are diagnosed with later stage disease compared to White women or Black men.23

FIGURE 4. Factors Contributing to Disparities in Bladder Cancer Care

**Type of Insurance**
- Compared to patients with bladder cancer who use private insurance, uninsured and Medicaid-insured patients are more likely to experience delays in treatment longer than 90 days and lower odds of treatment at a high-volume facility.24

**Travel Burden**
- Centers of excellence are concentrated in urban areas, limiting access for patients living in suburban and rural areas.25
- Median travel distance has increased from 11.8 miles to 20.3 miles for surgical care and from 6.5 miles to 8.3 miles for non-surgical care.25

**Provider Density**
- The regionalization of healthcare since the early 2000s has affected access to timely treatment.26
- Many states experience shortages in the number of practicing urologists.27
- Over 2,000 counties in the U.S. are without a urologist.28

**Type of Hospital Providing Care**
- Black patients are more likely to be treated at community hospitals than tertiary cancer centers, where there are sometimes resource gaps, such as shortages in the availability of Bacillus Calmette-Guerin, and are less likely to receive guideline-recommended treatment.29
- Differences in access to treatment for muscle invasive bladder cancer account for almost three quarters of the excess risk of death among Black patients.30

**Attitudes & Beliefs**
- Healthcare within equal-access systems does not eliminate disparities in stage at diagnosis by race, ethnicity, or gender.30
- Primary care and gynecology providers often attribute hematuria to urinary tract infection in women and will treat with antibiotics without undergoing further work-up.31
- Many women see urologists as “doctors for men” and prefer to see primary care providers or gynecologists for hematuria.31
- Implicit bias likely plays a critical role in structuring disparities in receipt of guideline-recommended care.31
